AIRCRAFT AIR CONDITIONING SYSTEM MIXER

BACKGROUND OF THE INVENTION

[0001] The application claims priority to U.S. Provisional Application No. 60/504,671, which was filed on September 22, 2003.

[0002] The present invention relates to an aircraft air conditioning system mixer, and more particularly, this invention relates to a mixer for mixing air from an air conditioning pack and other air.

[0003] Aircraft air conditioning systems provide conditioned air to the aircraft cabin and other locations throughout the aircraft. An aircraft air conditioning system pack takes fresh air from the exterior of the aircraft and conditions the air, for example by using an air cycle machine as is known in the art, for use throughout the aircraft.

[0004] The pack provides very cold air that must be mixed with recirculated air to provide to the aircraft cabin. For example, a mixer takes the conditioned air and mixes it with cabin circulation air, which is at a higher temperature than the conditioned air. The mixer is typically configured in a T-shape and occupies a large space. In the prior art, a large mixer is needed to achieve required mixing and to prevent the mixer from icing up, which results in a pressure drop in the mixer, decreased pack performance, and ice particles being distributed into the cabin. As ice builds up and restricts the flow of conditioned air through the mixer, the air cycle machine (ACM) speed decreases reducing the ability of the pack to produce cold air. To address this problem, the prior art uses a mixer that is approximately the size of a 55 gallon drum. As the cold air from the pack mixes with humid recirculation air,

the moisture in the recirculation air condenses and freezes causing ice to collect at the bottom of the mixer where it inhibits the flow of conditioned air through the mixer. Desirably, prior art mixers produce a uniform temperature of the mixed air at the outlet due to the large volume of the mixer.

[0005] Therefore, what is needed is a smaller mixer that is not subject to ice build up while producing a uniform mixed air outlet temperature.

SUMMARY OF THE INVENTION

[0006] The inventive air conditioning system mixer includes a fresh air tube defining a passage having an inlet receiving conditioned air from an air conditioning pack. The fresh air tube includes an outlet providing mixed air to a cabin of the aircraft. An outer tube at least partially surrounds the fresh air tube and receives recirculated air from the cabin. Multiple holes in the fresh air tube fluidly connect the outer tube to the fresh air tube.

[0007] The warm recirculation air surrounds the portion of the fresh air tube to heat it preventing ice from forming. The warm recirculation air entering the fresh air tube through the holes homogeneously mixes with the conditioned air from the pack to provide a uniform mixture of air within the fresh air tube, which further ensures the prevention of ice build up.

[0008] In applications where air is provided to a flight deck separately from the cabin, the mixer includes a flight deck supply tube that is arranged about an inner tube that is fluidly connected to the fresh air tube upstream of the holes. Trim air is fed into the flight deck supply tube and flows around the inner tube to heat the inner tube preventing ice build up.

[0009] Accordingly, the present invention provides a smaller mixer that is not subject to ice build up while producing a uniform mixed air outlet temperature.

[0010] These and other features of the present invention can be best understood from the following specification and drawings, the following of which is a brief description.

BRIEF DESCRIPTION OF THE DRAWINGS

[0011] Figure 1 is a schematic view of the inventive aircraft air conditioning system with the inventive mixer.

[0012] Figure 2 is a rear elevational view of the inventive mixer shown in Figure 1.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

[0013] An inventive aircraft conditioning system 10 is shown schematically in Figure 1. The system 10 includes an air conditioning pack 12 that provides fresh conditioned air from an ACM. The pack 12 receives the fresh air from an engine bleed valve, or more preferably, an electrically driven supercharger.

[0014] Conditioned air 14 from the pack 12 flows into the inventive mixer 16. Mixed air 18 exits the mixer 16 and enters an acoustic treatment device 20 to reduce the noise. Once treated, the mixed air 18 is delivered to an aircraft cabin 22. Recirculation air 26 from the cabin 22 is returned to the mixer 16 by a fan 28 where it is mixed with the conditioned air 14 to obtain the mixed air 18 within a desired temperature range.

[0015] Some aircraft configurations require the delivery of air to an aircraft flight deck 38 that is separate from the air delivered to the cabin 22. For such applications, the

mixer 16 receives trim air 30 from the pack 12 to mix with the conditioned air 14. The trim air 30 may be supplied from hot air upstream of the pack 12 and downstream from the engine or superchargers. The mixer 16 delivers conditioned air 32 to an acoustic treatment device 34 from which the conditioned air is delivered to the flight deck 38.

[0016] The inventive mixer 16 prevents ice from building up within the mixer which would reduce the efficiency of the pack while maintaining the uniform mixed air outlet temperature. The mixer 16 includes a fresh air tube 40 defining a passage 42 extending from an inlet 44 to an outlet 46. The inlet 44 receives conditioned air 14 from the pack 12. The outlet 46 delivers mixed air 18, which is a mixture of the conditioned air 14 and the recirculation air 26, to the acoustic treatment device 20.

[0017] An outer tube 48 at least partially surrounds the fresh air tube 40 to form a cavity 52. During operation of the system 10, recirculation air 26 flows through a recirculation air inlet 50 into the cavity 52, filling the cavity 52 with warm recirculation air 26. The warm recirculation air 26 conducts heat into the fresh air tube 40, which raises the temperature of the fresh air tube 40 preventing ice from forming. Multiple holes 54 are arranged about the circumference of the fresh air tube 40 to fluidly connect the fresh air tube 40 with the cavity 52. The warm recirculation air 26 flows from the cavity 52 through the holes 54 into the passage 42 where it homogeneously mixes with the conditioned air 14 producing mixed air 18 having a uniform temperature. The uniform temperature of the mixed air 18 prevents cold spots within the mixer 16 that could permit ice formation.

[0018] For applications having a separate air supply for the flight deck 38, the mixer 16 may include a flight deck supply tube 56 extending from the body of the mixer 16. An inner tube 58 extends at an angle from the fresh air tube 40 and is arranged within the

flight deck supply tube 56. The angle is less than 90° to enhance flow from the passage 42 to the inner tube 58. The passage 42 is larger in diameter than the inner tube 58 as the cabin 22 requires considerably more air flow than the flight deck 38. The tubes 56 and 58 are spaced from one another to form a cavity 60. Preferably, the holes 54 are arranged downstream from the inner tube 58 so that the recirculation air 26 does not mix with air to the flight deck 38.

[0019] Referring to Figures 1 and 2, a trim air tube 62 extends from a side of the flight deck supply tube 56 to deliver the trim air 30 to the cavity 60. The hot trim air 30 within the cavity 60 conducts heat into the wall of the inner tube 58 preventing ice from building up on this wall. The trim air and conditioned air meet and begin to mix at the end of the inner tube 58. As with the other inlets and outlets of the mixer 16, a duct 64 is connected to an outlet 66 of the flight deck supply tube 56 by clamps. The trim air and conditioned air may continue to mix within the duct 64.

[0020] The mixer 16 may be cast or molded from any suitable material. The inventive mixer is considerably smaller than prior art mixers, approximately nine inches in diameter and 2 ft. x 2 ft. x 2 ft. in volume, without compromising performance and reliability. Moreover, the inventive mixer is much lighter than prior art mixers.

[0021] Although a preferred embodiment of this invention has been disclosed, a worker of ordinary skill in this art would recognize that certain modifications would come within the scope of this invention. For that reason, the following claims should be studied to determine the true scope and content of this invention.
